

Problem 2 Liquefied natural gas

2.1

In the boiling point the pressure of methane is 1 atm. Then

$$P = 1 \text{ atm} = 1.01325 \text{ bar} \quad \text{Log}(1.01325) = 3.99 - 443/(T - 0.49)$$

$$T = 111.68 \text{ K}$$

2.2

The energy density is proportional to the moles of methane.

liquefied methane

$$d(\text{CH}_4) = 16\,800 \text{ tn}/40\,000 \text{ m}^3 = 420 \text{ kg/m}^3$$

gaseous methane

$$d(\text{CH}_4) = (300 \cdot 10^5 \text{ Pa}) \cdot (16 \cdot 10^{-3} \text{ kg/mol}) / (8.314 \text{ J/mol.K} \cdot 298 \text{ K}) = 193.74 \text{ kg/m}^3$$

$$\text{ratio } (\text{CH}_4 \text{ (l)}/\text{CH}_4 \text{ (g)}) = 420/193.74 = 2.17$$

2.3

The reaction is:

If pressure inside it is kept constant then:

$$T = -159 \text{ }^\circ\text{C} = 114 \text{ K} \quad \log(p) = 3.99 - 443/(114 - 0.49) = 0.0873$$

A phase diagram show that:

$$U_L = 0.1 \text{ kJ/mol} \text{ and } U_G = 7.35 \text{ kJ/mol} \text{ at } \text{Log}(p) = 0.0873$$

$$\text{Now } \Delta U_{\text{vap}} = U_G - U_L = 7.35 - 0.1 = 7.25 \text{ kJ/mol} \text{ and}$$

$$\Delta H_{\text{vap}} = \Delta U_{\text{vap}} + R \cdot T \cdot \Delta n_g = 7.25 \text{ kJ/mol} + 8.314 \cdot 10^{-3} \text{ kJ/mol.K} \cdot 114 \text{ K} \cdot (1 - 0) = 8.20 \text{ kJ/mol}$$

2.4

$$\text{heat leakage} = 50 \text{ kW} \cdot (1000 \text{ J} \cdot \text{s}^{-1}/\text{W}) \cdot 15 \text{ days} \cdot (24 \cdot 3600 \text{ s}/\text{day}) = 6.48 \times 10^{10} \text{ J}$$

$$n(\text{CH}_4 \text{ evaporated}) = 6.48 \times 10^{10} / 8.20 \times 10^3 = 7.90244 \times 10^6 \text{ mol}$$

$$n(\text{CH}_4 \text{ total}) = 16800 \text{ ton} \cdot (1000 \text{ 000 g}/\text{ton}) \cdot (1 \text{ mol}/16 \text{ g}) = 1.05 \times 10^9$$

$$\% \text{ evaporated} = (7.90244 \times 10^6 / 1.05 \times 10^9) \cdot 100\% = 0.753 \%$$

2.5

In this case the volume is constant then

$$m \text{ CH}_4 = 16\,800 \text{ ton}/3 = 5\,600 \text{ ton}$$

$$n \text{ CH}_4 = 5\,600 \text{ ton} \cdot (1\,000\,000 \text{ g}/\text{ton}) \cdot (1 \text{ mol}/16 \text{ g}) = 3.5 \times 10^8 \text{ mol}$$

$$Q = \Delta U$$

$$Q = 50 \text{ kW} \cdot (1000 \text{ J} \cdot \text{s}^{-1}/\text{W}) \cdot 9 \text{ month} \cdot (30.5 \text{ days}/\text{month}) \cdot (24 \cdot 3600 \text{ s}/\text{day}) = 1.186 \times 10^{12} \text{ J}$$

Let α the fraction of methane evaporated, then a phase diagram show that:

$$U_L \text{ initial conditions (114 K and } \text{Log}(p) = 0.0873) \text{ is } 0.1 \text{ kJ/mol}$$

$$U_G \text{ final conditions (} \text{Log}(p) = 16.4) = 1.215) \text{ is } 7.9 \text{ kJ/mol}$$

$$U_L \text{ final conditions (} \text{Log}(p) = 16.4) = 1.215) \text{ is } 2.9 \text{ kJ/mol}$$

Now

$$Q = 1.186 \cdot 10^{12} = \Delta U = U_{\text{final}} - U_{\text{initial}} = (3.5 \cdot 10^8 \text{ mol}) \cdot (7.9\alpha + 2.9(1 - \alpha) - 0.1) \text{ kJ/mol} \cdot (1000 \text{ J}/\text{kJ})$$

$$3.3886 = 5.0\alpha + 2.8 \rightarrow \alpha = 0.1177$$

2.6

Maximum temperature is the critic temperature at the critic pressure. Phase diagram show that:

$$\text{Log}(\text{critic pressure}) = 1.7, P_c = 50.12 \text{ bar} \text{ and } \text{Log}(p) = 3.99 - 443/(T - 0.49) = 1.7 \quad T_c = 194 \text{ K}$$
