

## AUSTRALIAN CHEMISTRY OLYMPIAD

## FINAL PAPER

PART A

1988

## Instruction to candidates

(1) You are allowed $\mathbf{1 0}$ minutes to read this paper, and $\mathbf{2}$ hours to complete the questions.
(2) You are not permitted to refer to books, notes or periodic tables but you may use an electronic calculator and molecular models.
(3) You must attempt all questions.
(4) Answers must be written in the blank space provided immediately below each question in the exam booklet. Rough working must be on the backs of pages.
(5) Answers must provide clearly laid out working and sufficient explanation to show how you reached your conclusions.

## Question 1

(a): Methylmercury(II) cation, $\mathrm{CH}_{3} \mathrm{Hg}^{+}$, is the 'heavy' metal cation responsible for the toxicity episodes at Minamata, Japan, and elsewhere during the 1960s and 1970s.

Its chemistry is relatively simple. In aqueous solution, the $\mathrm{CH}_{3} \mathrm{Hg}^{+}(\mathrm{aq})$ cation is acidic, losing a proton to form a hydroxy complex:

$$
\mathrm{CH}_{3} \mathrm{Hg}^{+}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \quad \rightleftharpoons \quad \mathrm{CH}_{3} \mathrm{HgOH}+\mathrm{H}^{+} \mathrm{K}_{1}=-4.607
$$

The cation can further react with $\mathrm{CH}_{3} \mathrm{HgOH}$ to form a binuclear species:

$$
2 \mathrm{CH}_{3} \mathrm{Hg}^{+}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons\left(\mathrm{CH}_{3} \mathrm{Hg}_{2}\right)_{2} \mathrm{OH}^{+}+\mathrm{H}^{+} \quad \log \mathrm{K}_{2}=-2.234
$$

In poisoned humans, methylmercury(II) is found primarily inside red blood cells, where its concentration (in all forms) is approximately $10^{-6} \mathrm{M}$.

Assuming that a red blood cell contains only water at pH 7.4 (a little simplistic!), calculate the proportions of the three methylmercury(II) species present.
(b): Of course a red blood cell is somewhat more complicated than just described, but as far as a $\mathrm{CH}_{3} \mathrm{Hg}^{+}$cation is concerned, apart from water, the only other small complexing agents with significant concentrations are chloride $(0.154 \mathrm{M})$ and the tripeptide glutathione ( 0.002 M ).

Glutathione is a tetraprotic acid with $\mathrm{pK}_{\mathrm{a}} \mathrm{s}$ of $2.12,3.53,8.66$ and 9.62 at the ionic strength of a blood cell. The structure of the fully protonated form of glutathione (GS-H4+) is shown below:

Draw the structures of:
(i) fully deprotonated glutathione (the form which exists in aqueous solution at pH 12 ).
(ii) the major form or forms of glutathione at a physiological pH of 7.4.
(c): The equilibrium constants for the formation of methylmercury(II) complexes with chloride and with the fully deprotonated form of glutathione (GS) are:

|  | $\mathrm{CH}_{3} \mathrm{Hg}^{+}+\mathrm{Cl}^{-}$ | $\rightleftharpoons$ | $\mathrm{CH}_{3} \mathrm{HgCl}$ |
| :--- | :--- | :--- | :--- |$\quad \log \mathrm{K}_{3}=4.90$

Draw the structures of the methylmercury(II) species present in a red blood cell at pH 7.4 , in order of their decreasing abundance. Consider water, chloride and glutathione as the only potential complexing agents.

## Question 2

(a): Using benzene together with one other aromatic molecule of your choice and any inorganic reagents you wish, suggest a synthesis for

b): cis-2-Phenylcyclohexyl-p-toluenesulfonate (1) reacts with the strong base potassium tertbutoxide in tert-butyl alcohol at $50^{\circ} \mathrm{C}$ to give exclusively 1 -phenylcyclohexene (2). trans-2-Phenylcyclohexyl-p-toluenesulfonate (3) does not give any of the alkene under the same conditions. Draw clear structures for the compounds (1) to (3) and explain the observations.
[ Note: tert-butyl alcohol is alternatively named 2-methylpropan-2-ol ]
(c) An aliphatic compound $\mathbf{A}$ is a very useful solvent and an industrial reagent. It contains $66.7 \% \mathrm{C}, 11.1 \% \mathrm{H}$, and $22.2 \% \mathrm{O}$. Upon reduction of $\mathbf{A}$ a secondary alcohol $\mathbf{B}$ is formed. It contains $64.9 \% \mathrm{C}, 13.5 \% \mathrm{H}$, and $21.6 \% \mathrm{O}$. A compound $\mathbf{C}$ is prepared from bromoethane with magnesium in dry ether. When the product of the reaction between $\mathbf{A}$ and $\mathbf{C}$ is hydrolysed a compound D containing $70.6 \% \mathrm{C}, 13.7 \% \mathrm{H}$, and $15.7 \% \mathrm{O}$ is formed.
[Relative atomic masses: $\quad \mathrm{C}=12.01 \quad \mathrm{H}=1.00 \quad \mathrm{O}=16.00$ ]
(i) Give the empirical formulae of $\mathbf{A}, \mathbf{B}$ and $\mathbf{D}$.
(ii) Deduce the molecular and structural formulae for $\mathbf{A}$ to $\mathbf{D}$. Give your reasoning. How would you verify your deductions?
(d): 4-Nitrophenol is a stronger acid than phenol itself. Using arguments based on mesomeric and inductive effects provide a rationalization for the observed facts.

## Question 3.

(a) Write electronic configurations for each of the following species. How many unpaired electrons does each have in the ground state?
(i) P
(ii) $\mathrm{O}^{+}$
(iii) Cr
(iv) Mn
(v) $\mathrm{Co}^{3+}$
(b) For any three of the following molecules, draw the Lewis structure (including resonance structures where applicable), predict the molecular structure and describe the bonding (in terms of hybrid orbitals).
(i) $\mathrm{BCl}_{3}$
(ii) $\mathrm{O}_{3}$
(iii) $\mathrm{NO}_{2}^{-}$
(iv) $\mathrm{XeOF}_{4}$
(v) $\mathrm{OCN}^{-}$
(c) For each of the following classical coordination compounds name and draw all the possible geometric and optical isomers. [en $=\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$ ]
(i) $\quad \mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{SCN})_{2}$
(ii) $\quad\left[\mathrm{Cr}(\mathrm{en})\left(\mathrm{NH}_{3}\right)_{2} \mathrm{I}_{2}\right] \mathrm{I}$
(iii) $\mathrm{K}\left[\mathrm{Co}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$
(d) The $\mathrm{d}^{6} \mathrm{Co}^{3+}$ complex ions $\mathrm{CoF}_{6}^{3-}$ and $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}^{3+}$ are different in colour and have different magnetic properties. Explain these differences using the crystal field model.

## Question 4.

(a) A forensic chemist is given a white solid that is suspected of being pure cocaine $\left(\mathrm{C}_{17} \mathrm{H}_{21} \mathrm{NO}_{4}\right.$, mol. wt. $\left.=303.35\right)$. She dissolves $1.22 \pm 0.01 \mathrm{~g}$ of the solid in $15.60 \pm 0.01 \mathrm{~g}$ of benzene. The freezing point was lowered by $1.32 \pm 0.04^{\circ} \mathrm{C}$.
[Freezing point of benzene $=5.5^{\circ} \mathrm{C} ; \quad \mathrm{K}_{\mathrm{f}}=5.12^{\circ} \mathrm{C} . \mathrm{kg} \cdot \mathrm{mol}^{-1}$ ]
(i) What is the molecular weight of the substance? Assuming that the percentage uncertainty in the calculated molecular weight is the same as the percentage uncertainty in the temperature change, calculate the uncertainty in the molecular weight.
(ii) Could the chemist unequivocally state that the substance is cocaine? For example, is the uncertainty small enough to distinguish cocaine from codeine $\left(\mathrm{C}_{19} \mathrm{H}_{21} \mathrm{NO}_{3}\right.$, mol.wt. 299.36)?
(b): Consider the following galvanic cell:

$$
\mathrm{Pb}\left|\mathrm{~Pb}^{2+}(0.10 \mathrm{M}) \| \mathrm{VO}^{2+}(0.10 \mathrm{M}), \mathrm{V}^{3+}\left(10^{-5} \mathrm{M}\right), \mathrm{pH}=1.00\right| \mathrm{Pt}
$$

At $25^{\circ} \mathrm{C}$ the measured cell potential is +0.67 V .
(i) Calculate the standard reduction potential $\left(\mathrm{E}^{\circ}\right)$ for the $\mathrm{Pb} / \mathrm{Pb}^{2+}$ couple at $25^{\circ} \mathrm{C}$, given that $\mathrm{E}^{\circ}$ for the $\mathrm{VO}^{2+} / \mathrm{V}^{3+}$ couple is +0.39 V at $25^{\circ} \mathrm{C}$.
(ii): Because we now know $\mathrm{E}^{\circ}\left(\mathrm{Pb} / \mathrm{Pb}^{2+}\right)$, we can use a lead electrode as an analytical tool to measure the concentration of $\mathrm{Pb}^{2+}$ ions in a sample of polluted mine water.

Our analytical tool will be the galvanic cell containing lead and hydrogen electrodes:
$\mathrm{Pb} \mid$ water sample containing $\mathrm{Pb}^{2+}, \mathrm{pH}=2.00 \mid \mathrm{H}_{2}(\mathrm{~g}), \mathrm{Pt}$

The measured potential of this analytical cell is +0.090 V when the partial pressure of $\mathrm{H}_{2}$ is 1.00 atm. What is the concentration of $\mathrm{Pb}^{2+}$ in the mine water?
[ Nernst Eqn.: $E=E^{\circ}-\frac{0.0592}{n} \ln Q$ ]
